Automation & QA Developer — Task 1

Application Tested

- Demo App: RealWorld Demo Application
- URL: <https://demo.realworld.io>
- Testing Type: Manual QA & Functional Testing

Bug Report Table

#	Title / Summary	Steps to Reproduce	Expected vs Actual	Severity	Suspected Cause
1	Login button occasionally becomes unresponsive	Open login page → Enter credentials → Click login multiple times quickly	Expected: User should log in successfully every time. Actual: Login button sometimes freezes and no feedback is shown.	High	Missing loading/error state handling in frontend API request.
2	Signup form accepts weak/invalid email formats	Open signup page → Enter invalid email like abc → Submit form	Expected: Validation error should appear. Actual: Form sometimes accepts invalid input.	Medium	Improper frontend validation rules.
3	User session remains active after logout	Login → Click logout → Refresh page	Expected: User should remain logged out. Actual: Session/token occasionally persists after refresh.	High	Authentication token not fully cleared from local storage/session storage.
4	Mobile UI layout overlaps on smaller screens	Open app in mobile responsive mode	Expected: Responsive layout should adapt correctly. Actual: Text and buttons overlap on smaller screens.	Medium	CSS responsiveness and flex/grid styling issue.

#	Title / Summary	Steps to Reproduce	Expected vs Actual	Severity	Suspected Cause
5	Slow loading when opening article feed	Open homepage and refresh multiple times	Expected: Feed should load quickly. Actual: Noticeable delay while fetching articles.	Low	Large API response and lack of loading optimization/caching.

Root Cause Analysis

Issue Selected

Login button becomes unresponsive during authentication.

Analysis

The login issue appears to happen when the frontend sends an authentication request to the backend API but does not properly handle delayed or failed responses. When users click the login button multiple times, the application either freezes temporarily or provides no visible feedback. This creates confusion because users cannot determine whether the request is processing or failed.

The likely root cause is missing state management for API requests and insufficient error handling in the frontend logic. The UI does not disable the login button during processing, which allows duplicate requests to be sent. Additionally, backend failures or timeout responses are not shown clearly to the user.

To fix this issue, the application should implement proper loading states, disable repeated clicks during authentication, and display clear error messages when authentication fails. Retry logic and request timeout handling would also improve the overall user experience.

Conclusion

The application works for basic functionality, but several usability, validation, responsiveness, and session-handling issues could affect production usage. Improving frontend validation, authentication handling, responsive UI design, and API performance would significantly improve reliability and user experience.
